1 Abstract

The 2021 Waterfowl Breeding Population Survey for Wisconsin was conducted from April 26–May 7 and followed methods of the North American Waterfowl Breeding Population and Habitat Survey. The information from this survey is used as part of the overall survey of breeding waterfowl in North America as well as in making state-level waterfowl management decisions. This survey has been conducted annually since 1973. While this survey was not conducted in 2020 due to the COVID-19 pandemic, data on Wisconsin waterfowl breeding populations are best interpreted as trends viewed over several years rather than as year-to-year changes.

Total non-linear basins were down 37.1% from 2019 in the Southeast Central (SEC) region and up 18.5% from the long-term, 48-year mean. In the Northern High Density (NHI) region, total non-linear basins were up 11.3% from 2019 and up 23.8% from the long-term mean. Non-linear basins were up 0.6% from 2019 in the Northern Low Density (NLO) region and up 36.3% from the long-term mean. Non-linear basins were down 49.8% from 2019 in the Southwest Driftless (SWD) region and down 3.9% compared to this region's long-term (24-year) mean. Total linear basins were up 1.5% from 2019 in the SEC region and up 27.7% from the long-term mean. In the NHI region, linear basins were up 11.6% from 2019 and up 30.2% from the long-term mean. NLO region linear basins were up 21.4% from 2019 and up 44.7% from the long-term mean. Linear basins were up 7.5% from 2019 in the SWD region and up 39.8% from the long-term mean.

The 2021 total breeding duck modeled population estimate of 527,766 was 6.8% higher than the 2020 modeled estimate of 494,046, and was 20.4% higher than the long-term mean. Overall, the total duck population estimate for 2021 was higher than what we have experienced over the last few years (2015–2019) and above the total duck numbers experienced in the prior 10 years. The mallard modeled breeding population estimate of 172,151 was 4.9% lower than the 2020 estimate of 181,070 and was 3.7% lower than the long-term mean. The blue-winged teal modeled breeding population estimate of 65,082 was 2.6% higher compared to the 2020 estimate of 63,440, but remains 37.6% lower than the long-term mean. At 205,206 the 2021 population estimate for wood ducks was 30.4% higher than the 2020 estimate of 157,347 and 141.1% higher than the long-term mean. The modeled Canada goose population estimate of 179,384 was 2.3% higher compared to the 2020 estimate of 175,267, and 69.9% higher than the long-term mean. The population estimate of "other ducks" was 106,879, which was 17.7% higher than the 2020 estimate of 90,780 and was 69.9% higher than the long-term mean.

2 Introduction

Decisions regarding hunting season structure and harvest limits in waterfowl management are based in part upon spring breeding pair surveys. The U.S. Fish and Wildlife Service's (USFWS) Waterfowl Breeding Population and Habitat Survey (BPOP) has been conducted for 67 years across the traditional survey area of the north-central United States, Canada and Alaska. The Wisconsin Waterfowl Breeding Population Survey–which is modeled after the BPOP–has been conducted for 48 years and provides a long-term record of waterfowl breeding trends and wetland counts in Wisconsin. These data are used at the national- and state-level for monitoring waterfowl populations and making management decisions. Wisconsin's breeding waterfowl survey data are included in the Waterfowl Population Status report published annually by the USFWS on continental waterfowl populations. In addition, mallard data from Wisconsin, Minnesota, and Michigan are combined with data from the traditional survey area as a basis for the USFWS's Adaptive Harvest Management report that is used to establish federal waterfowl season frameworks. At the state-level, waterfowl breeding survey data are used to inform annual hunting season regulations, identify long-term changes in population trends, and evaluate the impacts of habitat changes and management. This report provides a summary and analysis of the 2021 survey data in support of these efforts.

3 Methods

3.1 Study area and survey timing

The Wisconsin Waterfowl Breeding Population Survey employs a stratified sampling scheme modeled after the BPOP survey (Platte 1987) but modified for local conditions (March et al. 1973). The state is divided into four strata based on regional waterfowl densities and habitat attributes: the Southeast Central region (SEC), Northern High Density region (NHI), Northern Low Density region (NLO), and Southwest Driftless region (SWD; Figure 1). Fifty-five east-west oriented transects, each 30 mi in length and 1/4 mi-wide, were randomly selected in 1973 within the SEC ($n = 29$), NHI ($n = 13$), and NLO ($n = 13$) regions; transects in the SWD region ($n = 11$) were not added until 1997 due to low wetland density.

Transects are typically surveyed from May 1–20 to obtain accurate estimates of *local* breeding pairs. However, the start date may be adjusted to accommodate inter-annual variation in the timing of spring (i.e., to exclude migratory individuals and minimize the effects of leaf-out on observer visibility). To account for latitudinal differences in leaf-out and waterfowl breeding phenology, surveys are generally initiated in southern Wisconsin and northern transects are the last to be completed.

3.2 Data collection

Two crews of two observers–each experienced in waterfowl identification and waterfowl census procedures–performed the aerial surveys, with one crew assigned to the south half of the state and the other crew assigned to the north half. To minimize problems with observer bias, the same aerial observers are used for a minimum five-year period. In addition, surveys do not take place when winds exceed 25 mph or if other adverse weather conditions exist (e.g., snow, rain, fog, and smoke). Fixed-wing aerial surveys were conducted from a Cessna 182 aircraft, flying at 90–100 mph and 100–150 ft above ground level. During each transect flight, an observer recorded all observations of ducks, geese, coots, cranes, and swans from each side of the plane, while the observer on the north side of the plane recorded the number and type of occupied and unoccupied wetland basins.

Given the challenges of detecting and counting waterfowl from the air, segments of selected aerial transects are censused by ground crews to obtain a 'complete' count of all waterfowl present and calculate visibility (air-to-ground) correction factors (VCFs). Ground crews (2–4 individuals) cover every wetland basin within a transect segment on foot or by boat on the same day or within 2 days after the air count. Ground observers record waterfowl observations according to the same instructions for the aerial survey.

3.3 Data preparation

The Waterfowl Breeding Population Survey focuses on four priority waterfowl species: mallards (*Anas platyrhynchos*), blue-winged teal (*A. discors*), wood ducks (*Aix sponsa*) and Canada geese (*Branta canadensis*). All other duck species are pooled into a category of "other ducks" ("total ducks" combines these four priority species and "other ducks"). By 2004, wood duck populations had increased to a level where we were able to estimate them as a separate group rather than as part of "other ducks." Lesser scaup (*Aythya affinis*) and bufflehead (*Bucephala albeola*) are not included in population estimates because they rarely breed in Wisconsin and when counted are assumed to be in migration to more northern breeding areas. We also tallied counts for several other species of interest: American coots (*Fulica americana*), whooping cranes (*Grus americana*), sandhill cranes (*Antigone canadensis*), and trumpeter swans (*Cygnus buccinator*).

We note that this survey was not originally designed for surveying Wisconsin's resident Canada goose population due to their earlier breeding phenology. However, aerial counts of geese increased steadily from the mid-1980s through the early 2000s, making survey estimates useful indices of population trends. Human-goose conflicts resulting from a growing goose population increase the importance of tracking the population status of breeding geese in Wisconsin, and have been included in this report since 1986.

Prior to analysis, we calculated the total numbers of "indicated" birds for each transect based on the observation type (i.e., pairs, lone drakes, flocked drakes, and groups) and each species' breeding biology. In general, lone drakes, flocked drakes, and pairs are adjusted by a multiplier of two, while groups ($\geq$ 5 drakes) are not adjusted.

3.4 Statistical analysis

3.4.1 Visibility correction factors

The VCF (also referred to as R; see below) is the ratio of individuals counted by ground crews to the number of individuals counted by aerial crews from the same set of transects. VCFs are used as a multiplier to the aerial survey counts, and yield statewide, corrected abundance estimates. VCFs were calculated independently for all priority waterfowl species and "other ducks" by pooling data from all 26 air/ground transects. To quantify VCF precision, we calculated the coefficient of variation (CV), which provides a standardized measure of dispersion. We iteratively added prior years of survey data until a CV value $\leq$ 0.20 (and a robust VCF) was achieved.

3.4.2 Population estimates

To calculate species-specific and visibility-corrected abundance estimates in each region, we used the traditional formula developed by Smith (1995):

$$N = B \times A \times R \tag{1}$$

where B is the bird density per mi^2, A is the area of the survey region, and R is the visibility correction factor. We note that this procedure was only conducted for the four priority waterfowl species and "other ducks" (VCF-corrected estimates were summed across the groups to estimate "total duck" abundance).

Because these abundance estimates are imperfect counts (i.e., some combination of true population size and detection error), we elected to model annual trends using a Bayesian state-space modeling approach (Kéry and Schaub 2012). State-space models are hierarchical models that simultaneously account for process error (true population size change) and measurement error (survey biases), and are increasingly used to model ecological time series (Auger-Méthé et al. 2021). State-space models offer at least two important advantages. First, modeled survey estimates smooth out drastic annual changes in population estimates that are biologically unrealistic (e.g., mallard abundance changing from roughly 250,000 in 1999, 450,000 in 2000, and then 180,000 in 2001). Second, a Bayesian state-space model allows for prediction, even when counts are unavailable (e.g., when surveys were canceled in 2020 due to the COVID-19 pandemic). Therefore, in the following waterfowl summaries we reference abundance and percent changes in state-space estimates rather than the raw population estimates. However, for comparison and continuity with previous reports, we provide both estimate types in the associated tables and figures (state-space modeling was first implemented for the 2021 report). We report the mean population estimate and 95% credible interval (CI), which can be interpreted as saying '*the true population size has a 95% probability of falling within this range, given the observed data.*'

4 Results

4.1 Survey timing

We initiated the 2021 Waterfowl Breeding Population Survey on April 26. As in the past, the survey was initiated in the southern part of Wisconsin, progressing northward to account for the differences in phenology from south to north. The timing of the breeding waterfowl survey is always a challenge because variables such as weather, waterfowl phenology, and tree leaf-out all impact the timing, visibility and accuracy of the survey. Weather was not much of an issue leading up to the survey, with dry and warm conditions statewide and most of the lakes in northern Wisconsin free of ice by early April. Conditions were mostly dry throughout the duration of the survey, so there was little influence on the number of temporary wetlands, which we often see when there are significant rain events as the survey is being conducted. There were some concerns with leaf-out on transects in the north-central portions of the state, which can make it more difficult to observe birds in forested and shrub wetlands.

Aerial surveys were completed in 9 days from April 26 to May 7. The ground survey was completed in 7 days from April 26 to May 7. Across all transects used to calculate VCFs, paired aerial and ground surveys occurred within 2 days of each other.

4.2 Wetland counts

In the SEC region, total non-linear basins were down 37.1% from 2019 and were up 18.5% from the long-term (48-year) mean. Linear basins in the SEC region were up 1.5% from 2019 and up 27.7% from the long-term mean (Table 1). In the NHI region, total non-linear basins were up 11.3% from 2019 and up 23.8% from the long-term mean. Linear basins in the NHI region were up 11.6% from 2019 and up 30.2% from the long-term mean (Table 2). In the NLO region, total non-linear basins were up 0.6% from 2019 and up 36.3% from the long-term mean. Linear basins in the NLO region were up 21.4% from 2019 and up 44.7% from the long-term mean (Table 3). In the SWD region, total non-linear basins were down 49.8% from 2019 and down 3.9% from this region's long-term, 24-year mean. Linear basins in the SWD region were up 7.5% from 2019 and up 39.8% from the long-term mean (Table 4). Long-term wetland counts for each survey region are shown in Figure 2.

4.3 Waterfowl population estimates

2021 VCF and population estimate summary statistics for mallards, blue-winged teal, wood ducks, "other ducks," and Canada geese are provided in Table 5.

4.3.1 Mallards

The 2021 modeled mallard population estimate was **172,151 (95% credible interval [CI] = 124,444–230,409 individuals)**. This estimate is 4.9% lower compared to the previous year's modeled estimate and 3.7% lower than the long-term, 48-year mean (Table 6; Figure 3). As in previous years, the SEC still represented the largest portion of the breeding mallard population (48%) and was similar to that of 2019.

4.3.2 Blue-winged teal

The 2021 modeled population estimate for blue-winged teal was **65,082 (95% CI = 38,631–104,553 individuals)**. This estimate was 2.6% higher compared to the previous year's modeled estimate but remains 37.6% lower than the long-term mean (Table 6; Figure 4).

4.3.3 Wood ducks

The 2021 population estimate for wood ducks was **205,206 (95% CI = 118,136–308,529 individuals)**. This estimate was 30.4% higher compared to the previous year and was 141.1% higher than the long-term mean (Table 6; Figure 5). The breeding wood duck population showed significant gains in the 1980s and early 1990s and appears to be leveling off around 100,000 after peaking about 10 years ago but has shown an increasing trend over the past five years.

4.3.4 Other ducks

The 2021 modeled population estimate for "other ducks" was **106,879 (95% CI = 49,783–203,001 individuals)**. This estimate was 17.7% higher compared to the previous year and was 69.9% higher than the long-term mean (Table 6; Figure 6). In 2021, species comprising "other ducks" were: ring-necked duck (*Aythya collaris*; 43%), hooded merganser (*Lophodytes cucullatus*; 32%), common merganser (*Mergus merganser*; 13%), northern shoveler (*Spatula clypeata*; 7%), common goldeneye (*B. clangula*; 4%), gadwall (*Mareca strepera*; 1%), and ruddy duck (*Oxyura jamaicensis*; 1%).

4.3.5 Total ducks

The 2021 population estimate for all breeding ducks was **527,766 (95% CI = 387,346–708,325 individuals)**. This estimate was 6.8% higher compared to the previous year and is 20.4% higher than the long-term mean (Table 6; Figure 7).

4.3.6 Canada geese

Based on the most recent harvest derivations, the proportion of the Wisconsin Canada goose harvest that consists of temperate breeding (formerly 'giant') Canada geese is about 60%, with most of those birds representing Canada geese that breed in Wisconsin (Dooley 2017). This proportion indicates the continued importance of in-state breeding Canada geese in our overall fall harvest. The 2021 population estimate for Canada geese was **179,384 (95% CI = 126,984–246,678 individuals)**. This estimate was 2.3% higher than the previous year's modeled estimate and was 69.9% higher than the long-term, 35-year mean (Table 6; Figure 8). The long-term trend in goose numbers suggests a continued, gradual increase in their population.

4.3.7 American coots, cranes, and trumpeter swans

In 2021, observers counted a total of 107 coots, one pair of whooping cranes, and 77 sandhill cranes (Figure 9). Excluding groups of five or more, 107 trumpeter swans were recorded and the 2021 population estimate was **11,504 (95% CI = 4,893–22,295 individuals)**; Table 7; Figure 10).

† Aerial Visibility Correction Factor = ratio of number of species-specific individuals seen from the ground divided by the number seen from the air on air-ground segments, pooled across strata. To achieve a desirable coefficient of variation (CV) value in the aerial visibility correction factor, previous years of air-ground data were iteratively added until CV was <20%. In 2021, aerial visibility correction factors for mallards, blue-winged teal, wood ducks, Canada geese, and "other ducks" were derived using 2, 13, 6, 2, and 13 years of air ground data, respectively.

[a] Lesser scaup, bufflehead, and all non-duck/goose waterbirds are excluded from analysis. Common duck species categorized as "other ducks" include: ring-necked duck, common goldeneye, northern shoveler, hooded merganser, common merganser, gadwall, green-winged teal, and canvasback.

Table 6: Statewide breeding waterfowl population survey estimates and corresponding Bayesian state-space modeled estimates (highlighted in bold) in Wisconsin, 1973–2021.

Table 7: Annual statewide estimates of breeding Trumpeter swan abundance in Wisconsin, 2010–2021. Raw survey estimates and model-predicted estimates from a Bayesian state-space model are shown. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

	Trumpeter swan statewide annual trends	
Year	**Survey estimate**	**Modeled estimate**
2010	1,237	1,205
2011	1,408	1,478
2012	1,999	1,908
2013	2,292	2,345
2014	2,979	2,956
2015	3,679	3,666
2016	5,029	4,581
2017	4,833	5,142
2018	5,677	6,078
2019	6,106	7,195
2020		9,750
2021	11,197	11,504

8 Figures

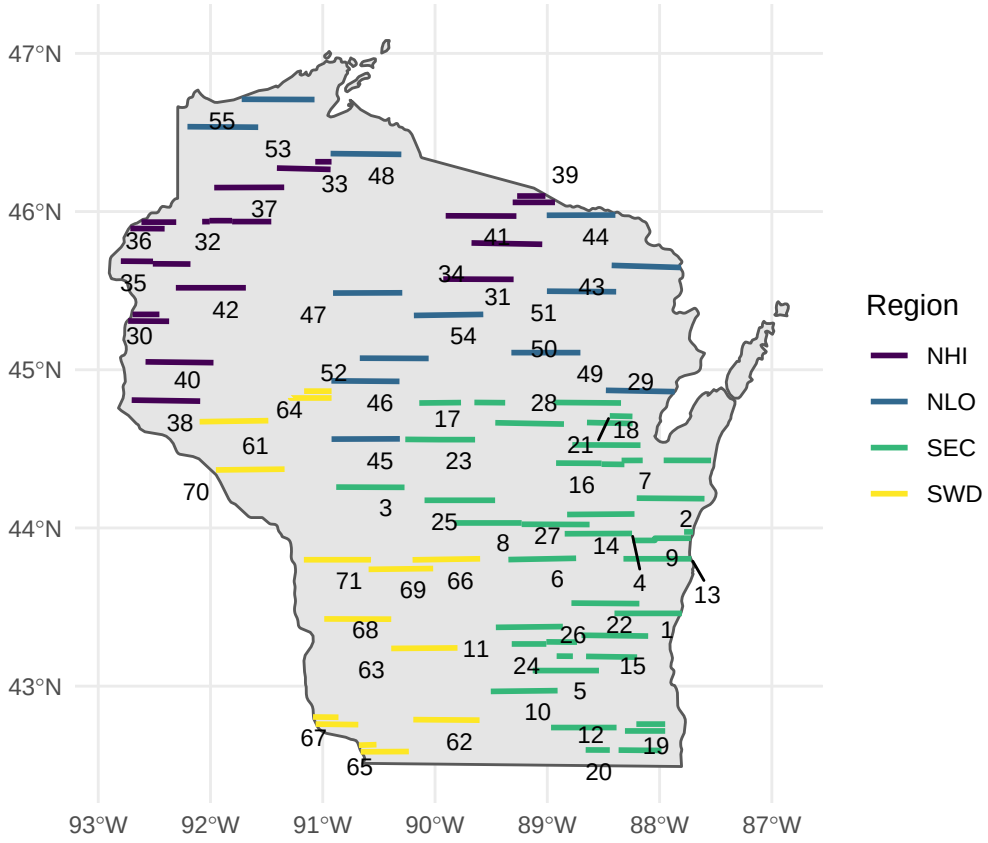

Figure 1: Wisconsin Waterfowl Breeding Population Survey aerial transects labeled by transect number and survey region. The four regions surveyed are the Northern High Density region (NHI), Northern Low Density region (NLO), Southeast Central region (SEC), and Southwest Driftless region (SWD).

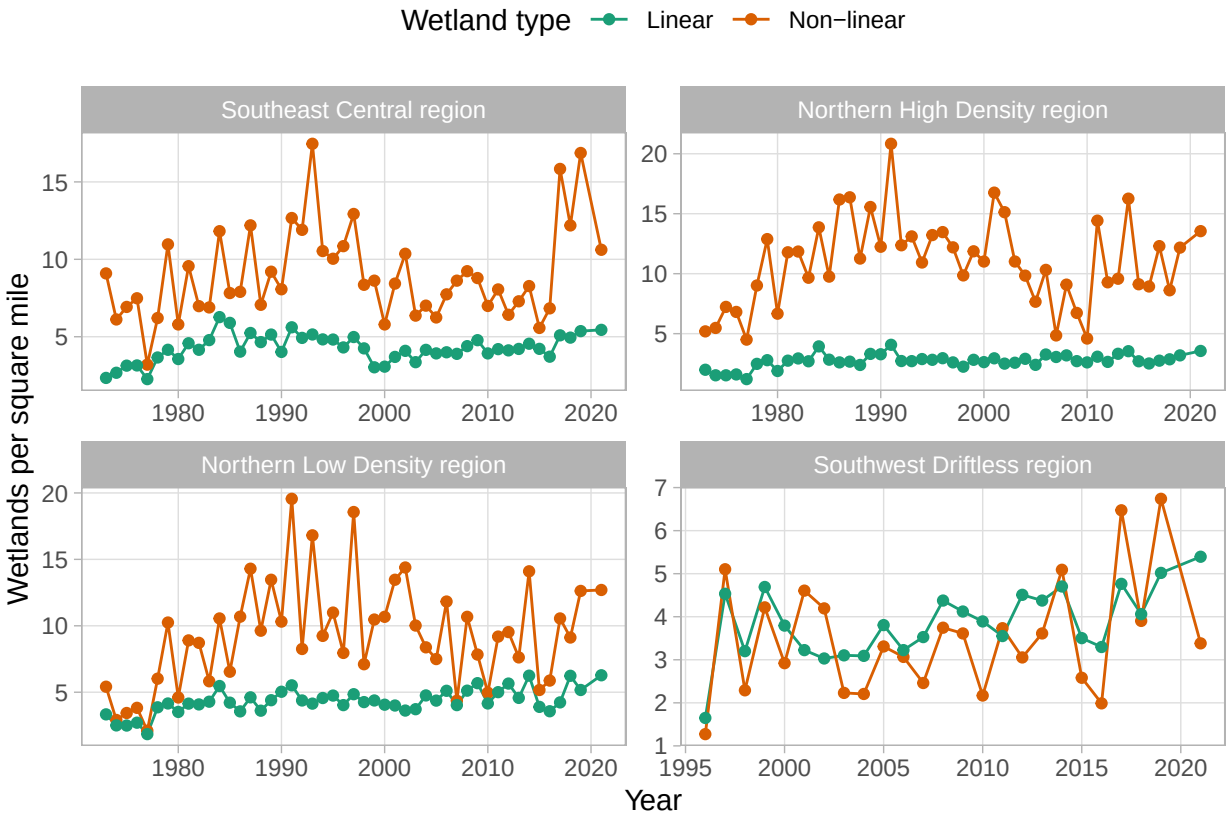

Figure 2: Annual variability in total non-linear and linear wetlands per square mile by survey region.

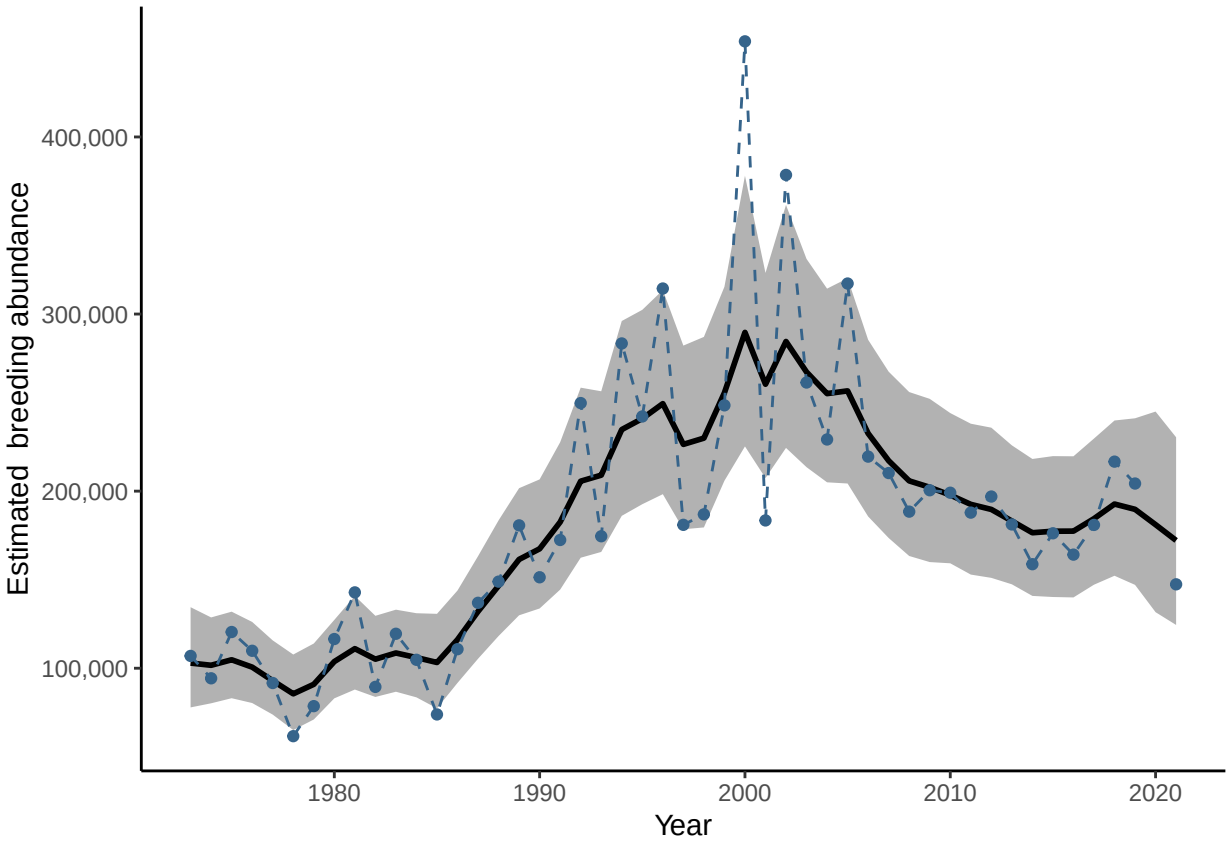

Figure 3: Annual statewide estimates of breeding mallard population size in Wisconsin, 1973–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

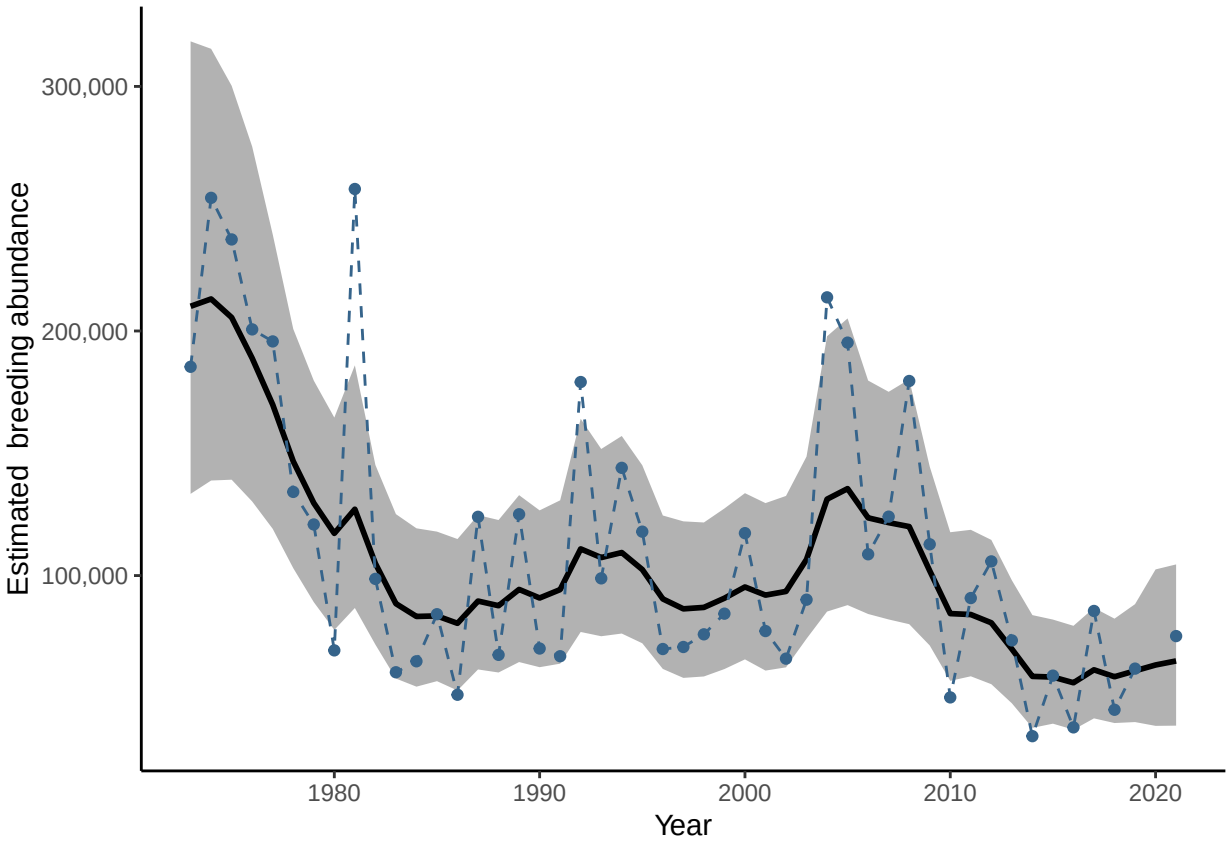

Figure 4: Annual statewide estimates of breeding blue-winged teal abundance in Wisconsin, 1973–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

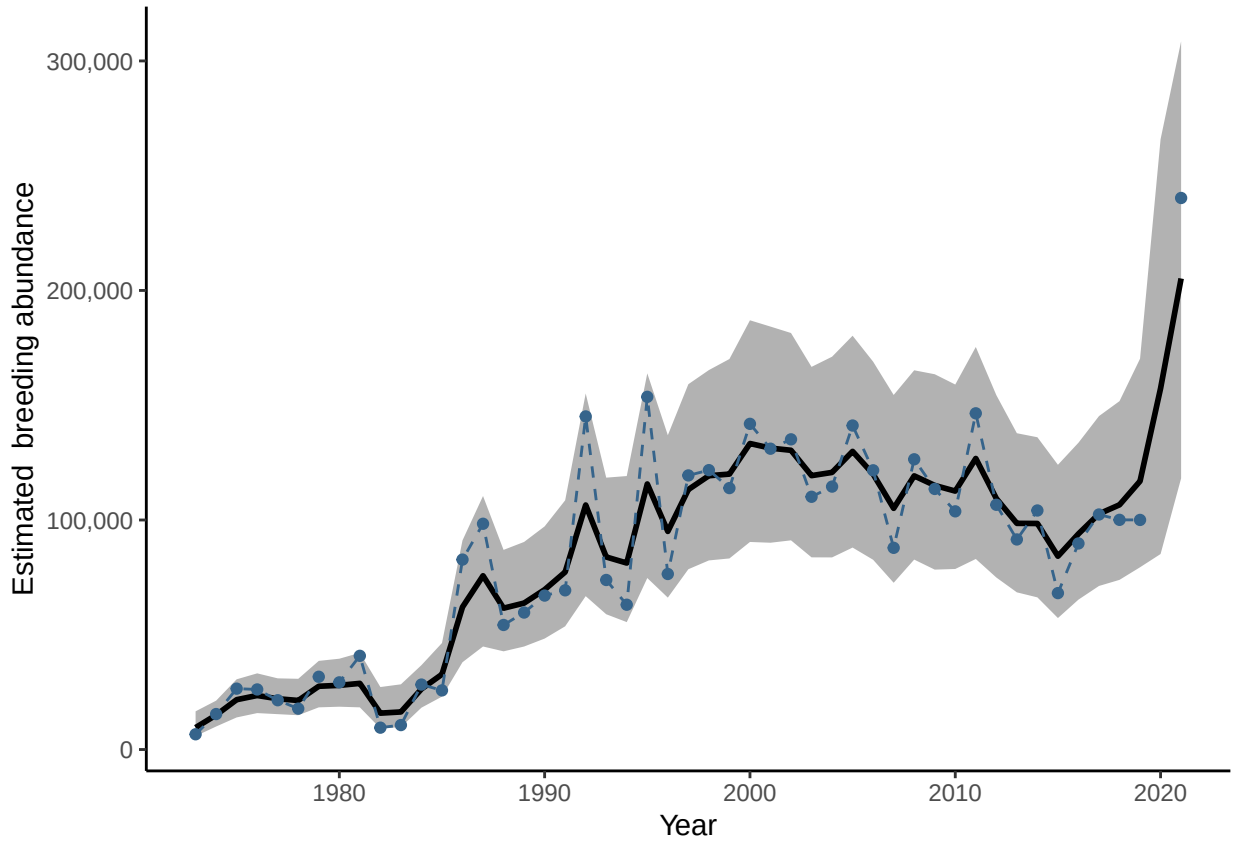

Figure 5: Annual statewide estimates of breeding wood duck abundance in Wisconsin, 1973–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

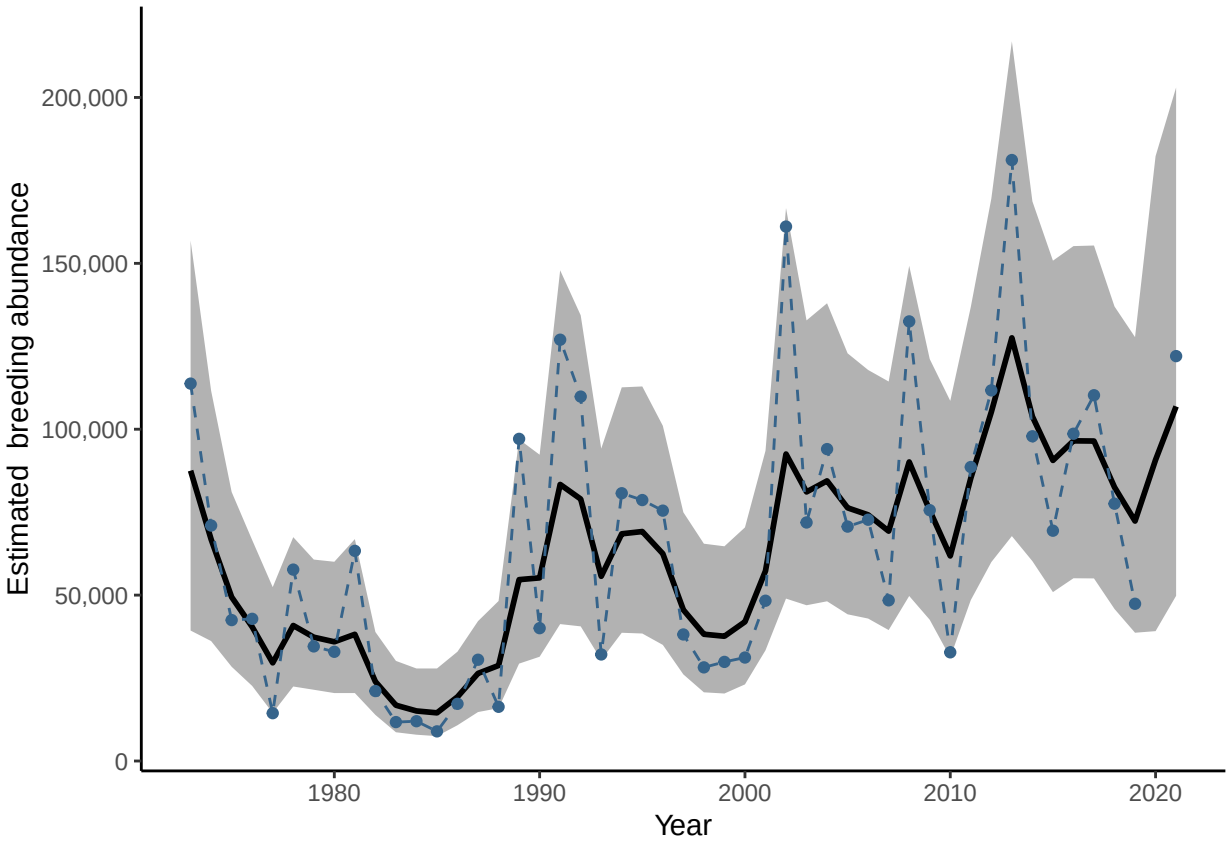

Figure 6: Annual statewide estimates of breeding 'other duck' abundance in Wisconsin, 1973–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

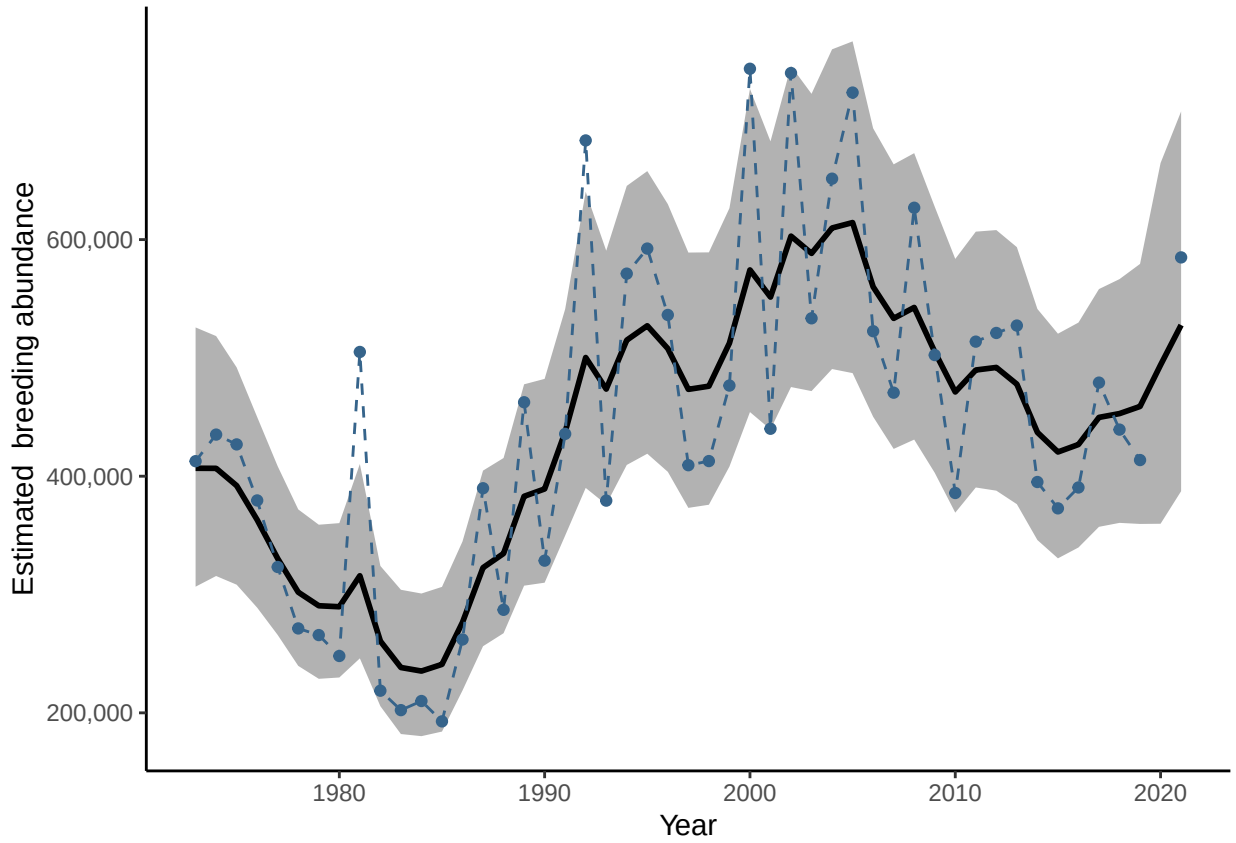

Figure 7: Annual statewide estimates of total breeding duck abundance in Wisconsin, 1973–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

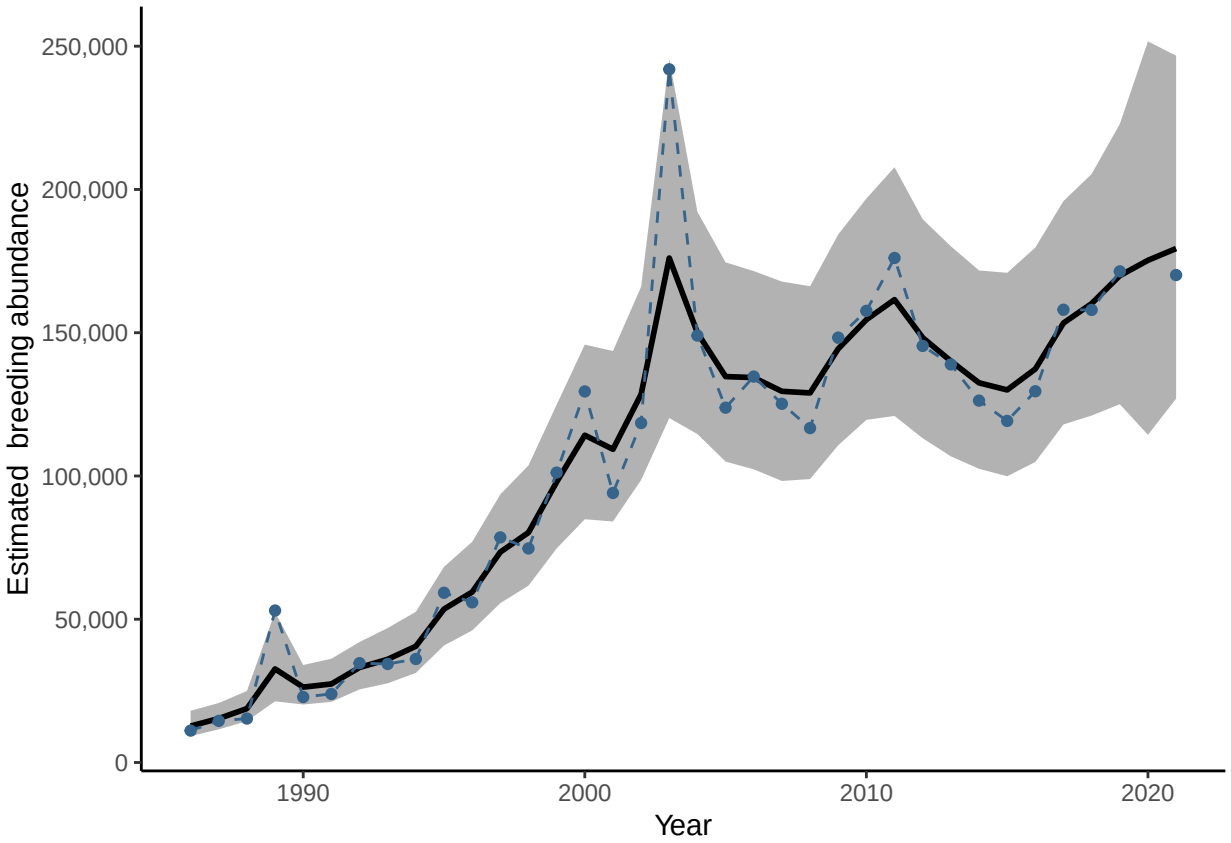

Figure 8: Annual statewide estimates of breeding Canada goose abundance in Wisconsin, 1986–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.

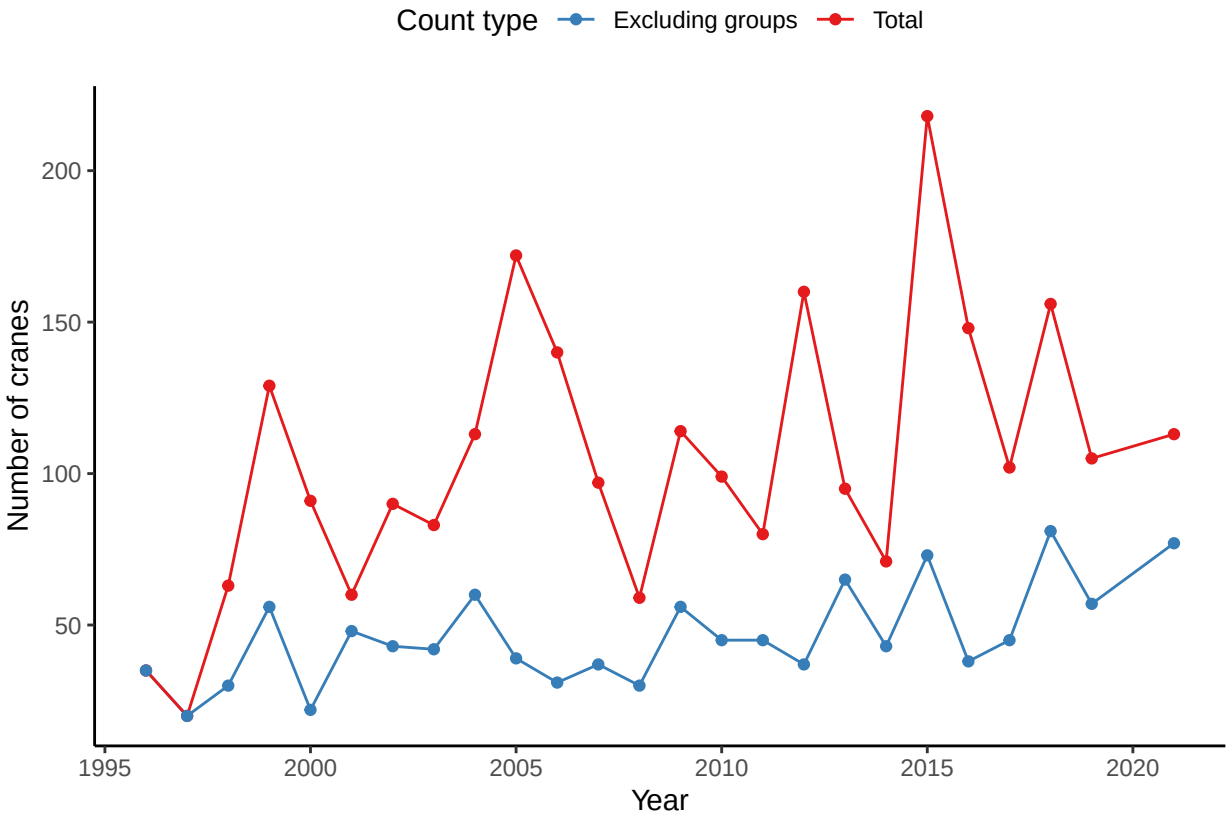

Figure 9: Annual counts of sandhill cranes observed from the air during the Waterfowl Breeding Population Survey, 1996–2021.

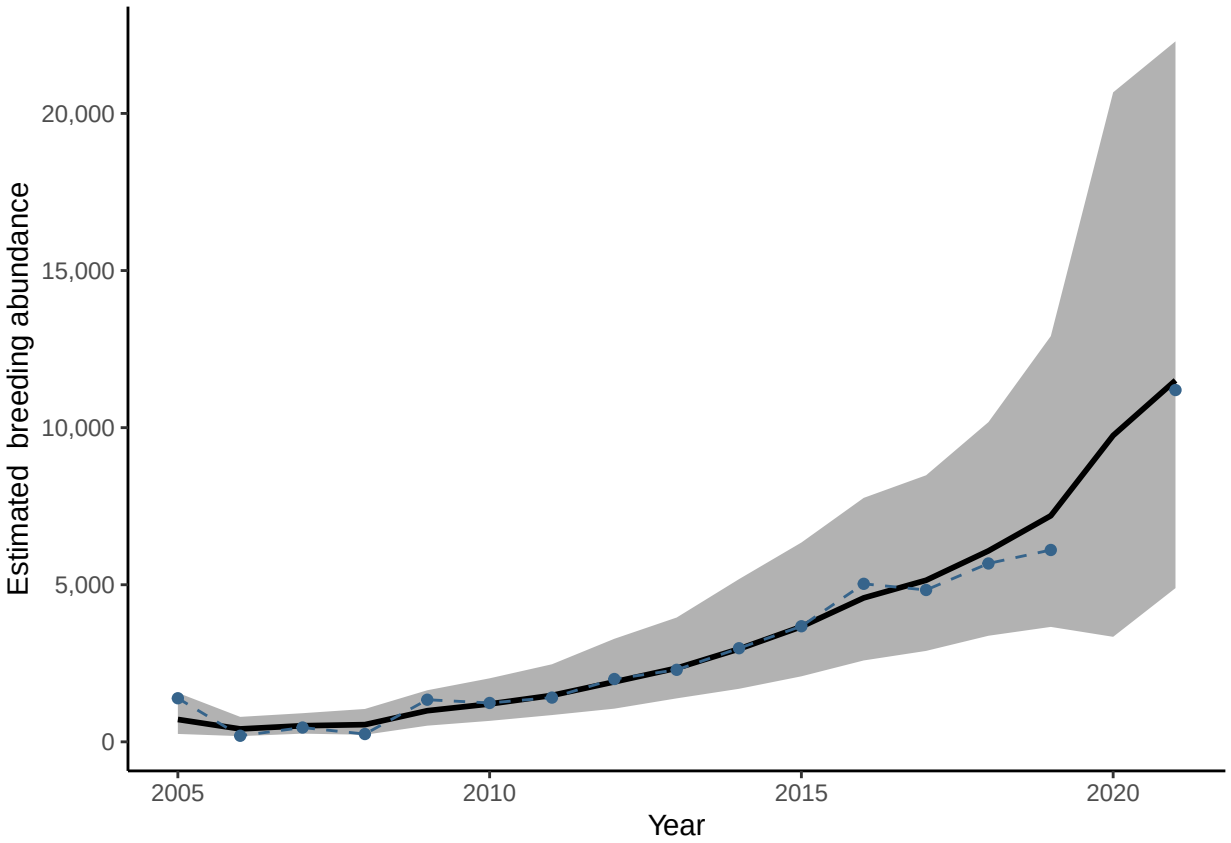

Figure 10: Annual statewide estimates of trumpeter swan abundance in Wisconsin, 2005–2021. Black line and gray shaded region are the mean and 95% credible interval estimates for the state-space population trend, and blue points and dashed line show the annual survey counts. Note that surveys were not conducted in 2020 due to the COVID-19 pandemic.
